TITLE: L-forms of some types of pathogenic bacteria

SOURCE: AMN SSSR. Vestnik, no. 8, 1965, 39-46

TOPIC TAGS: infective disease, bacteriology, microbiology

ABSTRACT: I. L-forms of mycobacteria.^{64,55} In recent years atypical forms of mycobacteria have frequently been isolated from tubercular patients. These differ in many significant ways from normal mycobacteria, yet are similar enough to be considered as merely atypical strains. One explanation for this transformation is that the atypical microbes arise from L-forms, which are themselves formed in response to the

L 12813-66

ACC NR: AP5028183

2

chemicals used in the treatment of tuberculosis. Several examples of just such transformations are noted in the literature. The purpose of the present study was to establish the conditions for L-transformation, to study the biological properties of the L-forms and their possible reversal to the bacterial form. One typical and one atypical strain were studied using several concentrations of dihydrostreptomycin, penicillin, or both as additives to the culture media. Cultures without antibiotics served as controls. The results (based on examination of live material and on differential staining) showed that L-forms are produced in response to both antibiotics, but the optimum conditions for transformation are when both antibiotics are present together. II. *L-forms of the family Corynebacteriaceae*. A study of the properties of the L-form of *Corynebacteriaceae* were undertaken with the hope of shedding some light on the connection of these bacteria with mycoplasma. Both toxigenic and non-toxigenic cultures of diphtheria and diptheroid organisms were used. It was found that L-form colonies were formed only on media containing 3 % liver agar with 20 % normal horse serum and penicillin. A detailed morphological description of the L-colonies is given. It is noted that subculturing resulted in almost total disappearance of normal rod-shaped bacteria which were found initially with some frequency. Certain cultures were found to revert to the rod-shaped diphtheria organisms without prior removal to a penicillin-free medium. The process of transformation

Card 2/3

L 12813-66

ACC NR: AP5028183

into atypical L-colonies is lengthy and requires from 2 weeks to 2-4 months. Other experiments showed that not all members of a given bacterial population are equally susceptible to transformation by penicillin in that only 5-7 strains of a 30-culture sample underwent transformation. Studies of the biochemical and cytopathogenic properties of the L-forms showed no consistent variations from those of the parent cultures. III. *L-forms of bacteria isolated from blood cultures of typhoid patients and carriers*. It has been established that L-forms can be isolated from a variety of bacterial infections; however, there is insufficient evidence on the formation of L-forms in active typhoid cases or carriers, although such transformations have been observed in this organism under laboratory conditions. To resolve this question defibrinated blood and bile of typhoid patients and carriers were cultured and examined. Of the 17 cases examined one patient and two carriers showed L-form growth in their blood cultures, while one patient had a mixture of L-forms and bacterial forms. Of particular interest was one patient whose blood originally yielded only typical *S. typhi*, but after intensive treatment with antibiotics granular elements of L-forms were isolated. This study showed that L-forms can indeed be formed in the body so now it remains to be determined what role they play in the development of the carrier condition. Orig. art. has: 4 figures.

AUTHOR: Shchegolev, D.M.

TITLE: Steam Boiler for a Solar Power Station

PERIODICAL: V sb.: Teploenergetika, No. 1, Moscow, AN SSSR, 1959, pp. 70-78

TEXT: The author presents the calculation methods for the steam boiler of the first solar power station of 15 t/hr steam capacity with the steam parameters of 30 at and 410°C. The peculiar feature of the boiler consists in the fact that it is mounted 35 m above the ground and rotates around a vertical axis with an average angular speed of 15°/hr. The boiler converts solar energy concentrated by the mirrors of the reflection installation. The author presents a description of the boiler design and the system of its automatic control. The efficiency of the boiler is 90.2-92.8%.

Translator's note: This is the full translation of the original Russian abstract.

Tashkent from October 5 to 8, 1960, which was actually a Scientific Conference on Helio-engineering. The Conference discussed the results of studies conducted, and laid down the main trends for further research. The following matters were discussed among others: theoretical reports on the transformation of solar energy by means of mono- and polycrystalline silicon photoelements as well as semiconductor thermocouples; results of physical investigations, the apparatus used, especially thermal ion converters; practical means to increase the efficiency of thermo- and photo solar batteries through concentrated solar radiation and the design of such converters; the possibilities and prospects of the application of solar energy for the acceleration of aging experiments with insulation materials; methods for the thermodynamic calculation of some solar installations of the sun. The construction of a solar furnace with a diameter of from 15 to 20 m for the investigation of heat-resistant alloys and ceramics at high temperatures was found to be necessary. This furnace is to be erected at the Fiziko-tekhnicheskiy institut Akademii nauk Uzbekskoy SSR (Physicotechnical Institute of the Academy of Sciences Uzbekskaya SSR). The suitability of constructing a solar caloric power station was confirmed. The Conference underlined

TITLE: Two-mirror solar stand of the ENIN

SOURCE: Geliotekhnika, no. 5, 1965, 5-10

TOPIC TAGS: photoelectric detection equipment, actinometry

ABSTRACT: A combined two-mirror heliostat-containing solar stand was constructed in 1961-1962 at the testing area of the ENIN. The paper gives a detailed engineering description of the stand as a whole and of its various components (the mirrors, heliostat, reducing gears, photoelectric tracking sensors, vacuum system, and actinometric mechanism). The stand is presently in satisfactory operation. [The specific uses and results are not given.] Orig. art. has: 7 figures. [JPRS]

Title : Photographic photometry and colorimetry of outer galactic nebulae

Periodical : Astron. zhur. 32/1, 16-21, Jan-Feb 1955

Abstract : Work, accomplished at the Pulkovo observatory in 1951-1953 is briefly described. The work consisted in determining the absolute values of brightnesses and colors of 15 outer galactic nebulae of the Sb and Sc types, namely: NGS 224, 598, 3031, 3623, 3627, 3628, 4192, 4217, 4254, 4258, 4321, 4565, 4631, 5194, 5457. The photographic method was used during this work. Six references: 3 USSR, 1 French, 1 Belg. (1933-1952). Graphs .

TITLE: Observations of the Second Earth's Artificial Satellite^V (1957 β) at
Station No. 039 (Pulkovo)

PERIODICAL: Byul. st. optich. nablyudeniya iskusstv. sputnikov Zemli, 1959, No.
6, pp. 1-5 (English summary)

TEXT: Results of observations and processing of photographs taken with two
standard cameras are described in detail. Coordinates were determined by the
method of A. A. Kiselev and partially by A. N. Deych's method. One "node" point
was obtained from one negative relative to which coordinates and time were inter-
polated several times. The following factors were taken into account: diurnal
rotation of the sky, refractional parallax of the sputnik, systematic errors in
measuring the edge of the sputnik track, track curvature and sputnik acceleration.
Relative time instants were reduced to the standard time of the USSR with \times

Card 1/2

allowance for the lag of the camera, chronograph and other units of the equipment, the run and corrections of the printing chronograph and quartz clock. Astrographic coordinates of the node points (68 in total) are published for the epoch of 1950.0; other data include: instant in the system of standard time and universal approximately-uniform time TU_2 , angular velocity and position angle of the sputnik motion, and some other data. The accuracy of the published time instant is characterized by the root-mean-square error of $\pm 0.005^s$; the inner (in distinction from the error of instants) accuracy of coordinates is $\pm 0.2^s$ sec δ and $\pm 3''$.

"A Map-Scheme of the Reverse Side of the Moon."

paper presented at IAU Symposium on the Moon, Leningrad, USSR, 6-8 Dec 60.

(1) The photographs of the reverse side of the Moon were reduced independently at the Pulkovo Observatory. The details were revealed by the projection method and only the most reliable formations noted. A map-scheme of the distribution ~~maps~~ of dark and bright objects, containing 107 details, was compiled.

(2) The comparison of the eastern region of the scheme with photographs and maps of the visible side of the Moon showed a high degree of reliability of detection of regions with low albedo which differs from that of the surroundings (maria, flooded ring mountains, ray systems). The detection of details of the relief is exceedingly difficult.

AUTHORS: Breydo, I. I., Markelova, A. A., and Shchegolev, D. Ye.

TITLE: The identification of authentic objects on the Moon's far side
by the first photographs taken of this side

SOURCE: Akademiya nauk SSSR. Iskusstvennyye sputniki Zemli. No. 9,
Moscow, 1961, 30-40

TEXT: The study was conducted to identify authentic details on the first photographs of the Moon's far side taken on October 7, 1959 by the automatic interplanetary station, to determine their selenographic coordinates, and on this basis to compile a map of the Moon's far side with an approximate distribution of the brightness of the revealed details. For this purpose, contact positives from negatives obtained by telerecording pictures of the Moon's far side, double-negatives obtained from the same negatives, and prints of pictures obtained from a magnetic tape were used. These prints were enlarged approximately 10 times. Lenses with focal lengths of 200 and 500 mm had been used for taking the pictures. The coordinates of

Card 1/3

S/560/61/000/009/001/009
D045/D114

The identification of authentic objects ...

The details of the lunar surface were determined by using the known coordinates of the automatic station at the moment of photographing, and calculation and tracing a network of selenographic coordinates in the external perspective projection. The terminator line, calculated according to the selenographic coordinates of the Sun at the moment of observation, was plotted into the network, and the angle of phase determined. The network copied and printed on diapositive plates was superimposed on a set of prints designed for determining the coordinates of the details of the Moon's far side. The diameter of the Moon's disk on these prints was 20 cm. A map-chart of the Moon's far side showing the approximate distribution of brightness of the revealed details is included. It is accompanied by a table in which all objects and details marked on the map are described as to their color and form. The map-chart was compared with maps and atlases of the visible side of the Moon and the border zones on the chart with photographs contained in the atlas of the Likskaya observatoriya (Likskaya Observatory). Since almost all the details plotted on the map-chart actually seemed to exist, it was assumed that the objects on the Moon's far side, plotted on the map-chart according to photographs taken by the automatic station, were authentic.

Card 2/3

The identification of authentic objects ...

S/560/61/000/009/001/009
D045/D114

Since the Moon, at the moment of photographing, was almost in its full phase, a larger part of the observed formations is distinguished from the surrounding area by its albedo. Therefore, the map-chart of the Moon's far side should be regarded as a chart of areas with different reflectivity and not as a relief map. Kh. I. Potter and T. A. Polozhentseva are thanked for assistance in calculating coordinate data. There are 2 figures, 3 tables and 3 references: 1 Soviet-bloc and 2 non-Soviet-bloc. The English-language reference is: H. P. Wilkins, P. Moore, The Moon, L., 1955. ✓

TITLE: An attempt at photometrically studying the nature of details on the surface of the Moon's far side

SOURCE: Akademiya nauk SSSR. Iskusstvennyye sputniki Zemli. No. 9, Moscow, 1961, 48-51

TEXT: A photometrical study of pictures of the Moon's far side, taken from the Avtomaticheskaya mezplanetnaya stantsiya (Automatic Interplanetary Station) (AMS), is conducted. The main task was to establish whether there is a diminution in brightness towards the edge of the photographed disk. In P. V. Makovetskiy's opinion, (Ref. 4: Astron. zh., 36, 487, 1959) the degree of brightness on the far side of the Moon should diminish towards the edges of the disk in view of reduced meteoric bombardment and less pitting on the surface. In order to verify this opinion, the authors measured a set of pictures diametrically, perpendicular to and along the "equator of intensity" and the TV scanning lines. A certain amount of darkening towards the

Card 1/4

32713
S/560/61/000/009/003/009
D045/D114

An attempt at photometrically studying ...

edge of the disk was observed only in the direction of the scanning band. This effect, apparently, was caused by the TV equipment. In other directions, no such diminution in brightness was observed. Therefore, it seems that the amount of pitting on both sides of the Moon is essentially the same. In this connection, the authors assumed that the brightness of details in the border zone observed, both from the Earth and the AMS at identical phase angles, are the same, and that these details may be used as an approximate calibrating scale. The brightness and reflecting power of details on the Moon's far side and in the border zone, calculated by the authors, are given in a table. The obtained values are highly approximate in view of considerable local distortions in density and the inadequacy of the calibrating scale. Nevertheless, the following preliminary conclusions can be made on the nature of certain formations on the Moon's far side: (1) The Sea of Moscow, the Border Sea, the Mare Smythii and eastern parts of the Mare Humboldtianum and the Southern Sea are typical marine depressions; in the area of the Border Sea and the Southern Sea there are many small, circular depressions similar to submerged craters with a dark floor. The western parts of the Mare Humboldtianum and the Southern Sea are somewhat brighter. The brightness of the Sea of Dreams is still greater and is not less

Card 2/4

D045/D114

An attempt at photometrically studying ...

than that of the lunar marshes. However, there may have been an instrumental error, leading to a reduction in the brightness of the given area; (2) the floor of Tsiolkovskiy's crater is darker than the darkest craters and seas - an unusual phenomenon which requires further checking; (3) a wide area with dark-gray and light-gray parts, located between the Mare Smythii and the Sovetskiy mountain range, in reflecting power is similar to a continent of average brightness with a predominance of marshes, semi-submerged craters and craters of the Ptolemaeus and Petavius types; (4) a light area near the north pole, stretching beyond the Sea of Moscow, is similar to a light continental shield encircling the crater Tycho and covered by many ring-shaped mountains; (5) the Giordano Bruno crater and the Sovetskiy mountain range are similar in reflecting power to the ray systems of Tycho and Copernicus. Considering that light bands similar to rays are emitted from them, it can be assumed that these areas are also groups of centers of ray systems; (6) judging by the results of the photo-measurements, it can be assumed that there is no essential difference between the two sides of the Moon as regards reflectivity and pitting. TRANSLATION: A proposed method of processing synchronous observations of artificial earth satellites from several points on the earth's surface is described. It is assumed that the coordinates of some of the points (not less than 2) are known relative to an initial reference ellipsoid, and that the coordinates of the remaining points are subject to determination. An equation is set up for the

sight line between the observer and the satellite in a three-dimensional coordinate system that is connected to the earth. Simultaneous solution of the equations for straight lines pertaining to different stations with known coordinates makes it possible to determine the spatial coordinates of the satellites. From the equations for the other stations one then determines the coordinates of these stations. It is pointed out that it is possible to use observations that are not strictly synchronous or observations that are not fixed exactly in a time scale that is the same for all the stations. In this case one includes in the data reduction two visible positions of the satellite, separated by an interval during which its motion can be assumed to be linear. It is indicated that account must be taken of the motion of the pole when calculating the spatial coordinates of the stations on the reference ellipsoid. Kh. Potter.

ABSTRACT: The Academy of Sciences of the socialist countries resolved in November 1962 to make synchronous observations on Echo-I. Such observations were made in May and June 1963. A single program was set up for all stations, and a computing center began sending out ephemeris telegrams. Observations began on May 22 and continued to June 29. Photographic observations were made in East Germany, Poland, Rumania, the Soviet Union, and Czechoslovakia. More than a thousand synchronous negatives were obtained. Stations were also set up in Siberia, Central Asia, the Far East, and other parts of the Soviet Union. Synchronous pairs were obtained for stations separated by over 5000 km (Alma-Ata and Yuzhno-Kuril'sk). Results of these observations are now being processed. Orig. art. has: 2 figures.

TOPIC TAGS: satellite Echo 1, artificial earth satellite, navigation aid, cosmic triangulation, space coordinate system, cartography, NAFA 3c/25c camera

ABSTRACT: The authors discussed the means and advantages of using the ECHO - 1 artificial earth satellite in the carrying out of cosmic triangulation. The principles involved were explained with reference to the schematic shown (see Fig. 1 on the Enclosure), wherein A and B are terrestrial observation stations with known coordinates. With stars in the background of the satellite at position S', both stations make simultaneous observations along sight lines AS' and BS', thus permitting solution of triangle AS'B and locating the satellite's position. If by similar means the position of the satellite is established at position S'' and simultaneously the satellite is observed from a third station N, then the location of station N can be fixed by solution of triangle S'NS''.
